# SUMMARY OF KEY FINDINGS FROM I-TRACK PHASE 3 (2010–2012)

This report provides an overview of findings from I-Track Phase 3 (2010–2012). The data in this report are shown for the overall sample as well as by sex allowing for comparisons between male and female participants. Where data in the table contain small cell counts,<sup>i</sup> the results should be interpreted with caution.

## Overview of I-Track

### WHAT?

I-Track is a behavioural and biological surveillance system that monitors the prevalence of HIV and hepatitis C as well as the associated risk behaviours among people who inject drugs in Canada. Information is collected through cross-sectional surveys conducted periodically at sentinel sites across Canada. Consenting participants are asked to complete an interviewer-administered questionnaire covering demographics, drug use and injecting behaviours, sexual behaviours, HIV and hepatitis C testing and treatment history, use of health services, and HIV-related knowledge. Participants are also asked to provide a biological sample which is tested for HIV and hepatitis C antibodies.

### WHO?

The target population is people who have injected drugs in the 6 months prior to recruitment and who meet the minimum age of consent as per provincial requirements. Participation is voluntary and completely anonymous.

### WHEN and WHERE?

Survey participants are recruited from sentinel sites across Canada. Surveys are conducted at regular intervals, generally every 3 to 5 years. The I-Track pilot was conducted from 2002–2003 in 4 sites, followed by 3 phases of data collection: Phase 1 from 2003–2005 in 7 sites, Phase 2 from 2005–2008 in 10 sites, and Phase 3 from 2010 to 2012 in 11 sites.

### WHY?

Certain risk behaviours, such as the sharing of needles and other injecting equipment as well as unprotected sex, are associated with transmission of blood-borne infections including HIV and hepatitis C among people who inject drugs. The ongoing monitoring of risk behaviours among people who inject drugs can therefore serve as an early warning system for the spread of blood-borne infections in Canada. In addition, the I-Track survey results can help inform and evaluate existing public health responses to HIV and hepatitis C among people who inject drugs in Canada.

---

<sup>i</sup> The definition of small cell size varies, but it is often defined as a cell count greater than zero but less than three, five, or six, depending on the nature of the data and the source.

### I-Track Phase 3 Sites

<sup>a</sup> The SurvUDI Network regions include Outaouais, Montréal, Québec City, Montérégie, Mauricie-Central Québec, Saguenay-Lac St-Jean, Eastern Townships, Abitibi-Témiscamingue and Ottawa (ON).

## Key Findings

**TABLE 1. Demographic characteristics of I-Track Phase 3 participants**

	<b>TOTAL<sup>a</sup></b> <b>(n=2687)</b>	<b>MALE</b> <b>(n=1832)</b>	<b>FEMALE</b> <b>(n=855)</b>	<b>p-VALUE</b>
<b>Age in years (n=2687)</b>				
Under 30	20.9% (561)	16.8% (307)	29.7% (254)	<0.001
30–49	60.8% (1635)	62.3% (1142)	57.7% (493)	
50 and over	18.3% (491)	20.9% (383)	12.6% (108)	
<b>Self-reported Aboriginal ethnicity (First Nations, Métis or Inuit) (n=2678)</b>	36.2% (968)	29.4% (537)	50.6% (431)	<0.001
<b>Sexual orientation (n=2673)</b>				
Heterosexual or straight	88.3% (2359)	91.9% (1679)	80.3% (680)	<0.001
Gay, lesbian, bisexual, two-spirit or other	11.7% (314)	8.1% (147)	19.7% (167)	
<b>Level of education (n=2679)</b>				
Completed some high school or less	55.7% (1492)	53.4% (974)	60.6% (518)	0.002
Completed high school	20.9% (560)	22.1% (403)	18.4% (157)	
Completed more than high school	23.4% (627)	24.5% (447)	21.2% (180)	
<b>Monthly income<sup>b</sup> (n=2641)</b>				
Less than \$500	14.4% (379)	12.3% (222)	18.7% (157)	<0.001
Between \$500–\$999	39.7% (1049)	40.3% (726)	38.4% (323)	
Between \$1000–\$1999	29.3% (775)	28.8% (518)	30.6% (257)	
\$2000 and more	16.6% (438)	18.6% (334)	12.4% (104)	
<b>Housing status at the time of interview<sup>c</sup> (n=2669)</b>				
Stable housing	61.3% (1637)	57.6% (1049)	69.3% (588)	<0.001
Unstable housing	38.7% (1032)	42.4% (772)	30.7% (260)	
<b>Proportion who had been incarcerated in the 6 months prior to interview<sup>d</sup> (n=2683)</b>	11.5% (308)	12.5% (229)	9.3% (79)	0.014
<b>Proportion who had ever lived in a correctional facility (n=2678)</b>	82.5% (2210)	88.5% (1618)	69.7% (592)	<0.001

<sup>a</sup> I-Track Phase 3 participants who indicated a sex at birth other than male or female (n=3) were excluded from the analyses presented in this report.

<sup>b</sup> This included all sources of income, both legal and illegal, during a one month period.

<sup>c</sup> Participants were asked to indicate where they were living at the time of the interview and responses were categorized as stable housing or unstable housing. Stable housing included: living in an apartment or house or a relative's apartment or house at the time of the interview. Unstable housing included: living in a friend's place, hotel or motel room, rooming or boarding house, shelter or hostel, transition or halfway house, drug treatment facility, correctional facility, public place (i.e., street, squats), psychiatric institution, hospital or any other responses that were considered unstable (i.e., vehicle, tent, anywhere outdoors).

<sup>d</sup> Participants were provided with a list of housing options and asked to select all the places where they had lived in the 6 months prior to interview; participants who selected a correctional facility (jail, corrections, prison) are presented here.

A total of 2,687 individuals participated in I-Track Phase 3 across 11 sentinel sites in Canada: Whitehorse YK, Prince George BC, Edmonton AB, Regina SK, Thunder Bay ON, Sudbury ON, London ON, Toronto ON, Kingston ON, the SurvUDI network (sites in the province of Quebec<sup>ii</sup> and Ottawa, ON), and Halifax NS.

The socio-demographic characteristics of Phase 3 participants were similar to those of previous I-Track phases; a large proportion of participants were male (68.2%) and the largest proportion of participants were between the ages of 30 and 49 years (60.9%), with a significantly higher proportion of male participants than female participants in this age group (62.3% versus 57.7%) and in the 50 and over age group (20.9% versus 12.6%). Although a large proportion of I-Track participants self-reported their sexual orientation as heterosexual or straight (88.3%), a significantly higher proportion of females than males self-identified as gay, lesbian, bisexual, two-spirit or other (19.7% versus 8.1%).

Over one-third (36.2%) of participants self-identified as Aboriginal (First Nation, Métis or Inuit), well above the proportion of self-identified Aboriginal people among the general Canadian population; based on 2011 data from the National Household Survey, 4.3% of the total Canadian population self-identify as Aboriginal.<sup>1</sup> There was substantial variation across sites with respect to the proportion of participants that self-reported their ethnicity as Aboriginal. For example, 89.6% of participants in Regina and 84.7% of participants in Edmonton self-identified as Aboriginal while only 19.1% of participants in London and 13.7% of participants in the SurvUDI network self-identified as Aboriginal. In addition, a significantly higher proportion of female participants across all sites self-identified as Aboriginal (50.6% of females versus 29.4% of males).

Over half (55.7%) of participants reported having less than a high school education, with a significantly higher proportion of female participants reporting a lower level of education as compared to their male counterparts. Over one-third (39.7%) of participants reported that their monthly income was in the range of \$500 and \$999, though there was considerable variation across participants and significant differences were noted between males and females.

Over one-third (38.7%) of all participants reported living in unstable housing at the time of the interview, with a significantly higher proportion of males reporting unstable housing. More than one-tenth (11.5%) reported having lived in a correctional facility in the 6 months prior to the interview; among males, this proportion (12.5%) was significantly higher as compared to females (9.3%). A large proportion of all participants (82.5%) reported that they had, at some time in their lives, been incarcerated; the proportion of males that reported a history of incarceration was significantly higher as compared to the proportion of females (88.5% versus 69.7%). Both unstable housing and incarceration present challenges to the prevention and control of HIV and other blood-borne infections among people who inject drugs in Canada as both are known as high-risk injecting environments.<sup>2,3</sup>

<sup>ii</sup> SurvUDI network sites in Quebec include Abitibi-Témiscamingue, Outaouais, Montréal, Montérégie, Québec City, Saguenay-Lac St-Jean, Mauricie-Central Québec, and Eastern Townships.

**TABLE 2. HIV and hepatitis C seroprevalence based on testing of biological specimens collected at the time of interview**

	TOTAL	MALE	FEMALE	p-VALUE
<b>HIV seroprevalence (among participants who provided a blood sample, n=2593)<sup>a</sup></b>				
HIV seropositive	11.2% (291)	11.6% (205)	10.4% (86)	0.387
Proportion of HIV seropositive participants who were aware of their HIV positive status (n=281) <sup>b</sup>	78.6% (221)	78.7% (155)	78.6% (66)	0.984
<b>Lifetime exposure to hepatitis C (among participants who provided a blood sample, n=2575)<sup>c</sup></b>				
Hepatitis C seropositive	68.0% (1750)	67.9% (1192)	68.1% (558)	0.899
<b>HIV and hepatitis C serostatus (among participants who provided a biological sample of sufficient quantity for testing of both HIV and hepatitis C antibodies, n=2575)</b>				
Seropositive for HIV only <sup>a</sup>	1.7% (43)	2.0% (35)	1.0% (8)	0.312
Seropositive for hepatitis C only <sup>c</sup>	58.5% (1505)	58.4% (1025)	58.6% (480)	
Seropositive for both HIV and hepatitis C <sup>a,c</sup>	9.5% (245)	9.5% (167)	9.5% (78)	
Seronegative for both HIV and hepatitis C	30.4% (782)	30.1% (529)	30.9% (253)	

<sup>a</sup> HIV testing of dried blood spot (DBS) specimens was performed using the AVIOQ HIV-1 EIA assay. Confirmatory testing was subsequently performed using the Bio-Rad GS HIV-1 Western Blot assay. A positive result indicated a current HIV infection.

<sup>b</sup> Participants who reported that their last HIV test result was positive and who were found to be HIV seropositive based on testing of the biological specimen provided at the time of interview were classified as being aware of their HIV positive status.

<sup>c</sup> Hepatitis C testing of DBS specimens was performed using the Ortho HCV version 3.0 EIA. Confirmatory testing was not performed for samples that tested positive. A positive result indicated past or present hepatitis C infection and did not discriminate acute from chronic or resolved infections.

Overall, HIV seroprevalence and lifetime exposure to hepatitis C infection were high; 11.2% of the survey participants who provided a biological sample of sufficient quantity for testing were HIV positive and 68.0% were seropositive for hepatitis C. No significant differences in HIV and hepatitis C seroprevalence were found between males and females. Though it is not possible to determine the proportion of participants that were co-infected with HIV and hepatitis C at the time of interview due to the nature of the laboratory test used (i.e., it was not possible to distinguish present from past hepatitis C infection), the non-significant proportion of participants who were seropositive for both HIV and hepatitis C (9.5%) nevertheless highlights the potential for multiple infections to complicate treatment responses as well as health outcomes among people who inject drugs in Canada.

The necessity of routine and integrated HIV and hepatitis C testing among people who inject drugs cannot be overstated. It was found that only 78.6% of I-Track Phase 3 participants who tested positive for HIV based on the biological sample provided at the time of interview were aware of their infection, or alternatively, that 21.4% of seropositive participants were unaware of their HIV positive status. Individuals who are unaware of their infection status are not able to benefit from treatment and counselling services and, moreover, cannot take measures to reduce their risk of HIV transmission to others. Furthermore, testing provides an opportunity to increase awareness of safe injection and sexual practices among people who inject drugs, as well as an opportunity to link individuals to available health and social support services.

TABLE 3. Drug use and injecting behaviours

BEHAVIOUR	TOTAL	MALE	FEMALE	p-VALUE
Proportion who first injected before the age of 16 years (n=2669)	15.4% (412)	14.0% (255)	18.5% (157)	0.003
Most commonly reported injection drugs used in the 6 months prior to interview <sup>a</sup>				
Cocaine	64.3% (1724)	66.0% (1206)	60.8% (518)	0.009
Hydromorphone	47.2% (1265)	47.1% (861)	47.4% (404)	0.890
Morphine (non-prescribed)	47.0% (1259)	45.0% (822)	51.3% (437)	0.002
Oxycodone	37.7% (1012)	36.8% (673)	39.7% (339)	0.143
Heroin	26.7% (716)	27.5% (503)	25.0% (213)	0.170
Most commonly reported person with whom participants injected in the 6 months prior to interview <sup>b</sup>				
No one (i.e., injected alone)	59.3% (1588)	60.2% (1101)	57.2% (487)	0.145
Friend(s) or people they knew well	50.5% (1354)	49.0% (896)	53.8% (458)	0.020
Regular sex partner(s) <sup>c</sup>	31.0% (831)	24.8% (453)	44.4% (378)	<0.001
People they didn't know well	17.8% (478)	18.1% (331)	17.3% (147)	0.604
Family member(s)	10.6% (285)	8.0% (147)	16.2% (138)	<0.001
Proportion who had used a sterile needle and/or syringe at last injection <sup>d</sup> (n=2663)	94.5% (2516)	94.7% (1721)	94.0% (795)	0.433
Proportion who had injected with a used needle and/or syringe in the 6 months prior to the interview (n=2671)	15.5% (415)	13.7% (249)	19.6% (166)	<0.001
Proportion who reported that their used needle and/or syringe had been subsequently used by someone else for injection in the 6 months prior to interview (n=2646)	15.5% (409)	12.7% (229)	21.4% (180)	<0.001
Proportion who had injected with other used injection equipment <sup>e</sup> in the 6 months prior to interview (n=2672)	34.5% (922)	31.6% (576)	40.9% (346)	<0.001
Proportion who reported that their other used injection equipment <sup>e</sup> had been subsequently used by someone else in the 6 months prior to the interview (n=2659)	33.1% (880)	29.7% (540)	40.3% (340)	<0.001
Most commonly reported location of injection in the 6 months prior to interview <sup>f</sup>				
Own apartment/house	61.1% (1642)	59.0% (1081)	65.6% (561)	<0.001
Friend's place	42.1% (1131)	40.4% (740)	45.7% (391)	0.007
Public place <sup>g</sup>	39.4% (1059)	41.8% (766)	34.3% (293)	<0.001
Hotel/motel room	15.6% (419)	14.6% (267)	17.8% (152)	0.080
Vehicle <sup>h</sup>	15.6% (419)	14.4% (263)	18.3% (156)	0.009
Rooming/boarding house	8.2% (220)	8.9% (163)	6.7% (57)	0.052

<sup>a</sup> Participants recorded all drugs that they had injected for non-medical purposes in the 6 months prior to interview. The most commonly reported drugs among all participants are presented. As participants could select more than one response, the total denominator is not shown.

<sup>b</sup> Participants indicated all types of people with whom they had injected in the 6 months prior to interview. The most commonly reported people are presented. As participants could select more than one response, the total denominator is not shown.

<sup>c</sup> A regular sex partner was defined as someone with whom the participant had a relationship and with whom the participant was emotionally involved.

<sup>d</sup> This measure is also used to contribute to the Global AIDS Response Progress Reporting Indicator 2.3.<sup>4</sup>

<sup>e</sup> Other used injection equipment included water, filters, cookers, spoons, tourniquets, ties, swabs, and acidifiers.

<sup>f</sup> Participants indicated all locations where they had injected drugs in the 6 months prior to interview. The most commonly reported locations among all participants are presented. As participants could select more than one response, the total denominator is not shown.

<sup>g</sup> Public place included street, park, squat, subway, etc.

<sup>h</sup> Vehicle included car, van, recreational vehicle, etc.

Several differences were noted between the drug use and injecting behaviours of males and females. Overall, 15.4% of all participants reported that they had injected drugs for the first time prior to the age of 16 years, with a significantly higher proportion of females than males reporting early use of injection drugs (18.5% versus 14.0%). Participants reported a variety of substances that they had injected in the 6 months prior to interview, though cocaine was the most commonly reported among all participants (64.3%). A significantly higher proportion of male than female participants reported injecting cocaine (66.0% versus 60.8%), while a significantly higher proportion of female than male participants reported injecting non-prescribed morphine (51.3% versus 45.0%).

With respect to the people with whom participants injected in the 6 months prior to interview, a significantly higher proportion of females reported injecting with friend(s) or people they knew well, regular sex partner(s) or family member(s). The high proportion of participants (59.3%) who reported injecting alone is of particular concern as injecting alone is a significant risk factor for overdose and death.<sup>5</sup>

While a large proportion (94.5%) of both male and female participants reported using a sterile needle at their last injection, a significantly higher proportion of female participants reported a history of high-risk injecting behaviours, including use of contaminated needles, syringes and/or other injection equipment, as well as passing on used needles, syringes and/or other used injection equipment to others. These findings, coupled with data from national routine surveillance which demonstrate that a higher proportion of female adults as compared to their male counterparts acquire HIV through injection drug use, suggest that females who inject drugs are particularly vulnerable to HIV infection.<sup>6</sup>

Participants reported a range of locations where they had injected drugs in the 6 months prior to interview, the most common of which was their own apartment or house; this location was reported by a significantly higher proportion of female than male participants (65.6% versus 59.0%). A significantly higher proportion of female than male participants also reported injecting drugs at a friend's place and in a vehicle. In contrast, a significantly higher proportion of male than female participants reported injecting drugs in a public place. Overall, 39.4% of all participants reported injecting in a public place which is of notable concern as public injection drug use is associated with high-risk injection practices and, in turn, increased risk of transmission of HIV and other blood-borne pathogens.<sup>7</sup>

TABLE 4. Sexual risk behaviours

BEHAVIOUR	TOTAL	MALE	FEMALE	p-VALUE
Proportion who had two or more sex partners in the 6 months prior to interview (n=2676)	34.4% (920)	31.3% (572)	40.9% (348)	<0.001
Proportion who had used a condom at last sex (among participants who reported sex in the previous month, n=2124)	36.6% (777)	37.2% (505)	35.4% (272)	0.401
Proportion who had a client sex partner <sup>a</sup> in the 6 months prior to interview (n=2687)	12.8% (343)	4.7% (86)	30.1% (257)	<0.001
Proportion who had used a condom at last sex with a client sex partner (n=306)	77.1% (236)	57.4% (35)	82.0% (201)	<0.001
Proportion who had been previously diagnosed with a sexually transmitted infection <sup>b,c</sup> (n=1732)	39.3% (680)	32.7% (355)	50.2% (325)	<0.001

<sup>a</sup> A client sex partner was defined as someone who has given the participant money, drugs, goods or anything else in exchange for sex.

<sup>b</sup> Defined as ever being told by a health professional (e.g. doctor or nurse) as having had chlamydia, gonorrhoea, human papillomavirus, genital herpes, oral herpes or another sexually transmitted infection.

<sup>c</sup> Data on the history of diagnosis with a sexually transmitted infection was not collected in the SurvUDI network.

Use of drugs has been shown to influence sexual behaviour by increasing risk taking; understanding the high-risk sexual behaviours (e.g., inconsistent condom use, multiple sex partners, sex trade work) of people who inject drugs in Canada is therefore of great public health importance.<sup>8</sup> Among I-Track Phase 3 participants who reported being sexually active, female and male participants differed in their sexual behaviours. A significantly higher proportion of female than male participants reported two or more sex partners in the 6 months prior to interview. Among participants who reported sex in the month prior to interview, reported condom use at last sex was similar between male and female participants, albeit quite low across all participants (36.6%). It should be noted that condom use at last sex was measured across all sex partner types. In comparison, reported condom use at last sex with a client partner was substantially higher (77.1%) and a significantly higher proportion of female than male participants reported this behaviour (82.0% versus 57.4%). A significantly higher proportion of female than male participants reported having a client sex partner in the 6 months prior to interview (30.1% versus 4.7%). History of a diagnosis of a sexually transmitted infection was significantly higher among female than male participants (50.2% versus 32.7%).

TABLE 5. Testing, care and treatment for HIV and hepatitis C

	TOTAL	MALE	FEMALE	p-VALUE
<b>HIV</b>				
Proportion who had ever tested for HIV (n=2657)	92.9% (2468)	91.9% (1668)	95.1% (800)	0.002
Proportion who had tested for HIV within the two years prior to interview (among participants who self-reported being HIV negative, n=2010)	85.0% (1709)	83.6% (1133)	88.1% (576)	0.008
Proportion who reported that they were under the care of a doctor for HIV at the time of interview <sup>a</sup> (among participants who self-reported being HIV positive, n=95)	95.0% (95)	94.2% (49)	95.8% (46)	0.713 <sup>b</sup>
Proportion who had ever taken prescribed drugs for HIV (among participants who self-reported being HIV positive, n=77)	77.0% (77)	80.8% (42)	72.9% (35)	0.351
Proportion who were taking prescribed drugs for HIV at the time of interview (among participants who self-reported being HIV positive, n=100)	66.0% (66)	75.0% (39)	56.3% (27)	0.048
<b>Hepatitis C</b>				
Proportion who had ever tested for hepatitis C (n=2646)	91.4% (2417)	90.3% (1625)	93.6% (792)	0.004
Proportion who reported that they were under the care of a doctor for hepatitis C at the time of interview <sup>c</sup> (among participants who self-reported being infected with hepatitis C at the time of the interview, n=1063)	48.4% (514)	49.3% (358)	46.3% (156)	0.359
Proportion who had ever taken prescribed drugs for hepatitis C (among participants who self-reported being infected with hepatitis C at the time of the interview, n=1060)	9.5% (101)	10.8% (78)	6.9% (23)	0.045
Proportion who were taking prescribed drugs for hepatitis C at the time of interview (among participants who self-reported being infected with hepatitis C at the time of the interview, n=1063)	2.4% (25)	2.6% (19)	1.8% (6)	0.402

<sup>a</sup> Defined as a single visit or more to a doctor for HIV treatment, counselling, testing, etc. in the 6 months prior to interview.

<sup>b</sup> Please note that due to small cell counts, results should be interpreted with caution.

<sup>c</sup> Defined as a single visit or more to a doctor for hepatitis C treatment, counselling, follow-up testing, etc. in the year prior to interview.

Most participants reported that they had ever tested for HIV and hepatitis C at some point in their lives (92.9% and 91.4%, respectively), and history of testing was significantly higher among female participants for both infections. No significant differences were found between male and female participants with respect to care and treatment for HIV, except that a significantly higher proportion of self-reported HIV positive male than self-reported HIV positive female participants reported that they were taking prescribed drugs for HIV at the time of the interview (75.0% versus 56.3%, respectively). Among participants who reported

being infected with hepatitis C at the time of the interview, low proportions reported being under the care of a doctor and taking prescribed drugs either at the time of the interview or in the past. No statistically significant differences were found between male and female participants in terms of care and treatment for hepatitis C, except that a significantly higher proportion of male than female participants reported that they had, at some time in their lives, taken prescribed drugs for hepatitis C (10.8% versus 6.9%, respectively).

**TABLE 6. Use of health services and level of difficulty accessing clean needles**

	TOTAL	MALE	FEMALE	p-VALUE
<b>Proportion who reported use of the following health care services in the 12 months prior to interview</b>				
Needle exchange or harm reduction facilities (n=1732)	89.0% (1541)	87.4% (948)	91.7% (593)	0.006
Hospitals (n=1732)	59.4% (1029)	57.9% (628)	61.9% (401)	0.105
Community drop-in centres (n=1733)	54.5% (945)	55.2% (599)	53.4% (346)	0.464
Medical clinics (n=1730)	47.1% (815)	42.7% (462)	54.6% (353)	<0.001
Community health centres (n=1735)	44.9% (779)	42.7% (464)	48.5% (315)	0.019
Detox or drug treatment facilities (n=1731)	32.2% (557)	31.9% (346)	32.6% (211)	0.765
Mental health and addictions centres (n=1729)	23.7% (409)	21.6% (234)	27.1% (175)	0.009
Culturally-based services (n=1729)	10.0% (173)	9.4% (102)	11.0% (71)	0.284
Sexual health centres (n=1727)	9.6% (165)	7.3% (79)	13.4% (86)	<0.001
<b>Self-reported level of difficulty accessing clean needles (n=2663)</b>				
Very easy	81.0% (2158)	82.2% (1493)	78.6% (665)	0.006
Somewhat easy	15.5% (413)	15.0% (272)	16.7% (141)	
Somewhat difficult	3.1% (83)	2.4% (44)	4.6% (39)	
Very difficult	0.3% (9)	0.4% (8)	0.1% (1)	

The provision of health and social support services to priority populations, including people who inject drugs, is an important component of Canada's response to HIV/AIDS and other blood-borne and sexually transmitted infections; understanding health service use among people who inject drugs in Canada is therefore of critical importance.<sup>9</sup> Use of health care services in the 12 months prior to interview varied depending on the health service in question; overall, needle exchange or harm reduction facilities were most commonly used among all participants (89.0%). Overall, health services use was higher among female participants; a significantly higher proportion of female participants reported accessing needle exchange or harm reduction facilities, medical clinics, community health centres, mental health and addictions centres and sexual health centres. A large proportion of participants (96.5%) reported that their level of difficulty accessing clean needles was either very easy or somewhat easy, and significant differences were noted between male and female participants.

TABLE 7. HIV-related knowledge

	TOTAL	MALE	FEMALE	p-VALUE
<b>Proportion of participants that correctly identified that:</b>				
<b>A healthy-looking person can have HIV (n=2626)</b>	98.4% (2584)	98.5% (1775)	98.2% (809)	0.542
<b>Using condoms reduces the risk of HIV transmission (n=2630)</b>	94.9% (2497)	96.0% (1730)	92.6% (767)	<0.001
<b>Currently, there is no cure for HIV/AIDS (n=2413)</b>	88.9% (2146)	88.4% (1460)	90.1% (686)	0.199
<b>A person cannot get HIV by sharing a meal with someone who is infected (n=2464)</b>	83.2% (2051)	83.3% (1403)	83.2% (648)	0.960
<b>Having sex with only one, faithful, uninfected partner reduces the risk of HIV transmission (n=2534)</b>	79.3% (2010)	81.3% (1421)	74.8% (589)	<0.001
<b>A person cannot get HIV from mosquito bites (n=2097)</b>	76.3% (1599)	75.4% (1106)	78.1% (493)	0.185

Understanding HIV-related knowledge and identifying common misconceptions surrounding HIV transmission facilitates the planning, implementation and evaluation of HIV/AIDS education strategies which play a vital role in the prevention and control of the disease. Overall, HIV-related knowledge varied according to the question being asked and, for select questions, significant differences were noted between the proportion of males and females that provided correct responses. Most participants (98.4%) correctly identified that a healthy-looking person can have HIV. A significantly higher proportion of male than female participants correctly identified that using a condom reduces the risk of HIV transmission and that having sex with only one, faithful, uninfected partner reduces the risk of HIV transmission. Of potential concern is that a relatively high proportion of participants (23.7%) inaccurately reported that a person can get HIV from mosquito bites.

## Conclusions

Overall, HIV seroprevalence and lifetime exposure to hepatitis C infection were high among I-Track Phase 3 participants. Although many participants reported safe injection and safe sexual practices (e.g., abstaining from using or sharing contaminated equipment, condom use, etc.), a high proportion of participants reported risk behaviours associated with acquisition and transmission of HIV and other sexually transmitted and blood-borne infections. These findings suggest that people who inject drugs continue to represent an important risk group in Canada's HIV epidemic, and highlight the need for continued treatment and prevention services, as well as routine and integrated testing among people who inject drugs.

There are some limitations to the I-Track findings, namely the survey used non-random sampling meaning that findings may not be representative of all people who inject drugs in any given site or in Canada as a whole. In addition, findings are based on self-reported data and it is therefore possible that certain risk behaviours were over or underrepresented. These limitations notwithstanding, findings from I-Track can be used to evaluate and improve existing health and social support services offered at the local, provincial and national level to people who inject drugs in Canada.

## Acknowledgements

The I-Track surveillance system is possible because of the successful collaboration between the Public Health Agency of Canada and provincial, regional and local health authorities, researchers, and community-based organizations. The authors gratefully acknowledge the contribution of the following:

- I-Track participants
- I-Track Site Principal Investigators: Michel Alary, Patricia Bacon, Patricia Caetano, Russell Callaghan, Holly D'Angelo-Scott, Murray Fyfe, Jennifer Gratrix, Brendan Hanley, Maurice Hennink, Pascale Leclerc, Dar Malaviarachchi, Peggy Millson, Carole Morissette, William Osei, Emma Palmantier, Élise Roy, Rita Shahin, Ron Shore, Ameeta Singh, Susan Snelling, Nathan Teegee, Maureen Twigg, Bryna Warshawsky, Gaynor Watson-Creed, John Wylie
- All site teams, including survey coordinators, interviewers and research assistants
- National HIV & Retrovirology Laboratories: Paul Sandstrom, John Kim, Laurie Malloch and Richard Pilon
- All members of the National I-Track surveillance team
